NEW PHENALKYLOXY-PHENYL DERIVATIVES

Field of invention

The present invention relates to certain phenalkyloxy-phenyl derivatives of formula I
5 and analogs, to a process for preparing such compounds, having the utility in clinical conditions associated with insulin resistance, to methods for their therapeutic use and to pharmaceutical compositions containing them.

Background of the invention

Insulin resistance, defined as reduced sensitivity to the actions of insulin in the whole
10 body or individual tissues such as skeletal muscle, myocardium, fat and liver prevail in many individuals with or without diabetes mellitus. The insulin resistance syndrome, IRS, refers to a cluster of manifestations including insulin resistance with accompanying hyperinsulinemia, possibly type 2 diabetes mellitus, arterial hypertension, central (visceral) obesity, dyslipidemia observed as deranged lipoprotein levels typically characterised by elevated
15 VLDL (very low density lipoproteins) and reduced HDL (high density lipoproteins) concentrations, the presence of small, dense LDL (Low Density Lipoprotein) particles and reduced fibrinolysis.

Recent epidemiological research has documented that individuals with insulin resistance run a greatly increased risk of cardiovascular morbidity and mortality, notably
20 suffering from myocardial infarction and stroke. In non-insulin dependent diabetes mellitus these atherosclerosis related conditions cause up to 80% of all deaths. In clinical medicine there is at present only limited awareness of the need to increase the insulin sensitivity in IRS and thus to correct the dyslipidemia which is considered to cause the accelerated progress of atherosclerosis.

25 Furthermore there is at present no pharmacotherapy available to adequately correct the metabolic disorders associated with IRS. To date, the treatment of type 2 diabetes mellitus has been focused on correction of the deranged control of carbohydrate metabolism associated with the disease. Stimulation of endogenous insulin secretion by means of secretagogues, like sulphonylureas, and if necessary administration of exogenous insulin are methods frequently
30 used to normalise blood sugar but that will, if anything,

further enhance insulin resistance and will not correct the other manifestations of IRS nor reduce cardiovascular morbidity and mortality. In addition such treatment involves a significant risk of hypoglycemia with associated complications.

Other therapeutic strategies have focused on aberrations in glucose metabolism or
5 absorption, including biguanides, such as methformin, or glucosidase inhibitors, such as acarbose. Although these agents have been efficacious to a degree, their limited clinical effect is associated with side effects.

A novel therapeutic strategy involves the use of insulin sensitising agents, such as the thiazolidinediones which at least in part mediate their effects via an agonistic action on
10 nuclear receptors. Ciglitazone is the prototype in this class. In animal models of IRS these compounds seem to correct insulin resistance and the associated hypertriglyceridaemia and hyperinsulinemia, as well as hyperglycaemia in diabetes, by improving insulin sensitivity via an effect on lipid transport and handling primarily in adipocytes, leading to enhanced insulin action in skeletal muscle, liver and adipose tissue.

15 Ciglitazone as well as later described thiazolidinediones in clinical development either have been discontinued reportedly due to unacceptable toxicity or show inadequate potency. Therefore there is a need for new and better compounds with insulin sensitising properties.

This step may be carried out in the presence of an inert solvent or in the absence of solvent in which case the temperature should be sufficiently high to cause at least partial melting of the reaction mixture, a preferred such temperature is in the range of 100°C to 250°C.

Where R⁴ is not hydrogen it is necessary to add a dehydroxylating agent in order to remove the formed -OH at the β carbon. Suitable reaction conditions and reagents are described in Synthetic Communications Smonou I et al., (1988) 18, 833, and Synthesis Olag G. Et al., (1991) 407, and J.Heterocyclic Chemistry Georgiadis, M. P. Etal., (1991) 28(3), 599-604, and Synth. Commun. Majeticj, G. et al. (1993), 23(16), 2331-2335, and Bioorg. Med. Chem. Lett. (1998) 8(2), 175-178.

Sometimes it is necessary, when R⁴ is H, to add a dehydrating agent such as p-toluenesulfonic acid in order to achieve the formation of the double bond.

In a typical such reaction the starting material of formula III and the compound of formula IV are combined in approximately equimolar amounts and molar excess, preferably 1-5 fold, of anhydrous sodium acetate and the mixture is heated until it melts if necessary under vacuum. The compound of formula IIb can then be isolated by mixing with water and acetone, followed by filtration of the formed precipitate. The crude product can be purified if desired, e.g. by recrystallization or by standard chromatographic methods.

- 16 -

This reaction can also be performed conveniently in a solvent such as toluene in the presence of piperidine acetate. The reaction mixture is refluxed in a Dean-Stark apparatus to remove water. The solution is then cooled and the olefin product isolated and purified, by standard methods.

5 The reaction can also be performed by mixing the starting material and the compound of formula V in dry THF, slowly adding potassium tert-butoxide at -20°C and quenching the reaction with acetic acid. The crude product is isolated and then dissolved in toluene and refluxed with p-toluenesulfonic acid in a Dean-Stark apparatus to remove the water. The product is then isolated and purified, by standard methods.

10 The reaction can also be performed in the presence of titanium (IV) chloride and pyridine in an inert solvent, such as chloroform.

The condensation step could also be performed as a Wittig-type reaction (cf. with a compound of formula IV Comprehensive Organic Synthesis vol. 1 p. 755-781 Pergamon Press).

15 Approximately equimolar amounts of reactants III and IV, are mixed in the presence of a base such as tetramethylguanidine or potassium carbonate in a 1-5 fold molar excess. This reaction may be carried out in the presence of an inert solvent such as dichloromethane or isopropanol at a suitable temperature (-10°C to +60°C) and at a time long enough.

The compound of the formula III is prepared by coupling a compound of the formula

20 VI

with a compound of the formula VII

25

in which formulas D, D', D'', R¹, m and n are as defined in Category A, at, for example alkylation conditions or by a Mitsunobu reaction (Tsunoda, Tetr. Lett. 34, 1639-42 (1993), when necessary followed by modifications of the D-groups as described in the experimental section.

- 5 The group Z can be - OH or a leaving group, such as halogen, sulfonate or triflate. The alkylation reaction and the Mitsunobu reaction can be carried out as described below or as in the experimental section.

The compounds of formula IV, V, VI and VII are either commercially available or can be prepared by standard procedures known to anyone skilled in the art from commercially
10 available starting materials or by analogous procedures described in this application.

- D. The reduction of the olefin version of the compound of formula I to the saturated version of a compound of formula I may be carried out by using a wide variety of reducing methods known to reduce carbon-carbon double bonds, such as catalytic hydrogenation in the presence of an appropriate catalyst, magnesium or sodium amalgam in a lower alcohol such as
15 methanol, or hydrogen transfer reagents such as diethyl-2,5-dimethyl-1,4-dihydropyridine-3,5-dicarboxylate.

The catalytic hydrogenation can be conducted in alcohol, cellosolves, protic polar organic solvents, ethers, lower aliphatic acids, and particularly in methanol, ethanol, methoxyethanol, dimethylformamide, tetrahydrofuran, dioxane, dimethoxyethane, ethyl
20 acetate or acetic acid, either used alone or in mixture. Examples of the catalyst used include palladium black, palladium on activated charcoal, platinum oxide or Wilkinson's catalyst. The reaction can proceed at different temperatures and pressures depending on the reactivity of the aimed reaction.

In case of hydrogen transfer reaction with diethyl-2,5-dimethyl-1,4-dihydropyridine-
25 3,5-dicarboxylate, equimolar amounts of reactants are mixed and the mixture is warmed to melting (140°C - 250°C) under inert atmosphere or under vacuum.

Pharmacological properties

15 The present compounds of formula (I) are useful for the prophylaxis and/or treatment of clinical conditions associated with reduced sensitivity to insulin (insulin resistance) and associated metabolic disorders. These clinical conditions will include, but will not be limited to, abdominal obesity, arterial hypertension, hyperinsulinaemia, hyperglycaemia, type 2 diabetes mellitus and the dyslipidaemia characteristically appearing with insulin resistance.

20 This dyslipidaemia, also known as the atherogenic lipoprotein profile, phenotype B, is characterised by moderately elevated non-esterified fatty acids, elevated very low density lipoproteins (VLDL) triglyceride rich particles, low high density lipoproteins (HDL) particle levels cholesterol and the presence of small, dense, low density lipoprotein (LDL) particles. Treatment with the present compounds is expected to lower the cardiovascular morbidity and
25 mortality associated with atherosclerosis. These cardiovascular disease conditions include macro-angiopathies causing myocardial infarction, cerebrovascular disease and peripheral arterial insufficiency of the lower extremities. Because of their insulin sensitizing effect the compounds of formula I are also expected to prevent or delay the development of type 2 diabetes and thus reduce the progress of clinical conditions associated with chronic
30 hyperglycaemia in diabetes type 1 such as the micro-angiopathies causing renal disease, retinal damage and peripheral vascular disease of the lower limbs. Furthermore the compounds may

be useful in treatment of various conditions outside the cardiovascular system associated with insulin resistance like polycystic ovarian syndrome.

1-Carbamoyl-1-ethoxy-2-[4-(2-{4-methylsulfonyloxyphenyl}ethoxy)phenyl]ethane (0.8 g, 1.96 mmol) was dissolved in THF (10 ml, dry) and the solution was cooled in an ice-bath. Borane-methyl sulfide complex (2.0 M solution in diethyl ether, 2.5 ml, 5 mmol) was added. After a while, the cooling-bath was removed. Starting material

(a) 2-Ethoxy-3-[4-(2-{4-methylsulfonyloxyphenyl}ethoxy)phenyl]propanoic acid

Lithium hydroxide hydrate (0.12 g; 2.82 mmole) dissolved in water (10 ml) was slowly added to a solution of ethyl 2-ethoxy-3-[4-(2-{4-methylsulfonyloxyphenyl}ethoxy)-phenyl]propanoate (described in Example 8) (1.12 g; 2.56 mmole) in THF (30 ml).
